Abstract

Marine oil spill incidents constitute one of the most severe threats to oceanic ecosystems, coastal economies, and maritime ecology. Timely, accurate, and legally defensible attribution of spill responsibility is essential for effective maritime law enforcement by the Indian Coast Guard. Existing surveillance solutions detect surface anomalies but fail to bridge satellite perception with physical drift modeling and vessel movement records. This project presents OASIS (Oil-spill Attribution & Satellite Intelligence System), an automated marine forensics platform. OASIS ingests Synthetic Aperture Radar (SAR) imagery, extracts oil slick masks via a custom U-Net deep learning model (achieving 81.0% mineral oil confidence), verifies detections against sea clutter look-alikes using an EfficientNet-B0 radiometric engine (Delta-dB contrast analysis), and reconstructs probable spill origins using Lagrangian leeway drift physics with Coriolis deflection. The calculated spatio-temporal origin envelope is correlated against a 58-million-record AIS vessel dataset using DuckDB in under 5 seconds to score candidate vessels on Closest Point of Approach (CPA), slick orientation alignment, and operational speed anomalies. The system delivers actionable forensic intelligence through a React 19 / MapLibre GL tactical interface and court-admissible PDF dossiers.

1. Introduction & Problem Statement

1.1 Background

Marine oil pollution resulting from operational tank washing, accidental collisions, and illegal bilge dumping inflicts catastrophic ecological damage on coastal wetlands, fisheries, and coral reefs. India's vast 7,516 km coastline and Exclusive Economic Zone (EEZ) host some of the world's densest international tanker shipping corridors, particularly across the Arabian Sea (Mumbai High to Gulf of Kutch) and the Bay of Bengal. Spaceborne Synthetic Aperture Radar (SAR), such as the European Space Agency's Sentinel-1 C-band constellation, represents the gold-standard imaging sensor for oceanic oil monitoring because microwaves penetrate cloud cover, rain, and operate day or night. Thin hydrocarbon films smooth short capillary and Bragg-scattering gravity ocean waves, causing specular reflection of radar pulses away from the sensor and manifesting as distinctive dark patches on SAR imagery.

1.2 Problem Statement

To develop an automated, end-to-end digital forensics platform that ingests Sentinel-1 SAR imagery and spatio-temporal metocean parameters, accurately segments marine oil spills, eliminates false-positive look-alikes via radiometric contrast analysis, deterministically hindcasts the spill's physical trajectory to its probable point of origin, and identifies responsible vessels from a 58-million-record AIS trajectory dataset.
Input: Sentinel-1 dual-pol (VV/VH) SAR tile, observation latitude/longitude, timestamp, and metocean wind/current vectors.
Expected Output: Pixel-level segmentation mask, geometric metrics (area km², centroid, elongation axis), 6-hour backward hindcast trajectory, 12-hour forward forecast dispersion cone, ranked suspect vessels with multi-factor forensic attribution scores, and a signed forensic PDF dossier.

1.3 Challenges

1. SAR Speckle & Look-Alikes: Biogenic slicks, algae blooms, low-wind calm sea patches (<3 m/s), and internal ocean waves create dark radar formations that mimic mineral oil slicks.
2. Hydrodynamic Drift Complexity: Slicks do not remain stationary; ocean surface currents and atmospheric leeway wind combine with Earth's Coriolis acceleration (+15° deflection in the Northern hemisphere) to continuously displace and diffuse the slick.
3. Big-Data AIS Spatiotemporal Indexing: Querying millions of historical vessel pings across multi-gigabyte maritime datasets to find intersecting trajectories within a tight spatial (±5 km) and temporal (±1 hour) origin window requires sub-second execution.
4. Dark Vessels: Rogue vessels engaging in deliberate discharge frequently disable their AIS Class-A transponders, demanding reliable non-fabrication safeguards and tactical interdiction coordinates.

1.4 Scope

The project encompasses dual-AI computer vision for SAR segmentation (U-Net) and radiometric patch verification (EfficientNet-B0), deterministic OpenCV geometry extraction (contour area, image moments, ellipse fitting), Lagrangian leeway drift physics, DuckDB in-process columnar AIS querying, multi-factor vessel attribution scoring, a React 19 tactical dashboard with MapLibre GL, and ReportLab forensic PDF generation. Out of scope: Onboard satellite hardware processing and active radar transmitter hardware design.

2. Review of Existing Systems & Feasibility

2.1 Existing Approaches

Existing remote sensing and maritime surveillance systems address isolated components of the spill response chain but fail to provide a unified, explainable attribution pipeline. Below is a comparative review of five prominent systems and tools:

2.2 Gap Identified

The critical capability gap is the absence of an integrated, automated, and legally defensible bridge between satellite perception (Layer 3), hydrodynamic drift physics (Layer 4), and vessel movement records (Layer 5). Current systems either detect slicks without attributing them (CleanSeaNet), apply AI segmentation without backward trajectory reconstruction (Cerulean), or log vessel tracks without

environmental correlation. OASIS addresses this by coupling deep-learning perception with deterministic Lagrangian advection and DuckDB spatiotemporal indexing into a single automated pipeline.

2.3 Feasibility

Technical Feasibility: Built entirely on robust open-source frameworks (Python 3.14, PyTorch, OpenCV, DuckDB, FastAPI, React 19). Runs on commodity 8GB RAM hardware with sub-10s end-to-end response time.

Data Feasibility: Leverages freely available Sentinel-1 C-band SAR data from ESA Copernicus, 58-million-record NOAA/MarineCadastre AIS datasets, and ECMWF/CMEMS metocean feeds.

Time Feasibility: Successfully completed within the academic semester timeframe, covering design, model training, physics verification, and UI implementation.

#	Method / Paper / Tool	Technique used	Strength	Limitation
1	EMSA CleanSeaNet	Threshold-based SAR segmentation & manual operator vetting	Proven operational surveillance coverage over European seas	High false-positive rate from look-alikes; no automated vessel attribution engine
2	SkyTruth Cerulean	Deep learning (U-Net) on global Sentinel-1 SAR imagery	Open-source, automated global slick detection platform	Lacks physics-based leeway hindcasting; cannot correlate with local AIS feeds
3	ESA SNAP Toolbox	Radiometric calibration, Lee speckle filter, manual thresholding	High scientific precision radar processing and polarimetry	Entirely manual desktop GUI; unusable for real-time tactical Coast Guard operations
4	Copernicus CMEMS	Ocean numerical circulation modeling & hydrodynamic reanalysis	High-resolution global ocean current and wind reanalysis	Raw oceanographic data feed only; contains no spill detection or vessel tracking
5	MarineCadastre AIS	Big-data spatiotemporal vessel trajectory GIS indexing	Comprehensive US/international vessel track visualization	Standalone GIS mapping tool; no coupling with satellite radar imagery or drift physics

3. Objectives & Methodology

3.1 Objectives

1. Develop and deploy a custom U-Net deep learning segmentation model achieving >80% mineral oil confidence on Sentinel-1 SAR scenes.
2. Implement an explainable Model 2 radiometric forensic verifier using EfficientNet-B0 and Delta-dB contrast analysis (Delta-dB > 3.0 dB threshold).
3. Extract metric geometric parameters (area in km², perimeter in km, spatial centroid, orientation angle) with sub-pixel contour accuracy.
4. Formulate a deterministic Lagrangian leeway drift engine with Coriolis deflection (+15° in NH) for 6h hindcast and 12h forecast.

5. Index and correlate a 58-million-record AIS database using DuckDB to achieve sub-5-second spatiotemporal candidate vessel retrieval.

3.2 Proposed Methodology

The OASIS architecture implements a 7-layer modular pipeline:

- Layer 1 (Ingestion): Ingests Sentinel-1 SAR tiles, ECMWF ERA5 wind vectors, CMEMS ocean currents, and AIS trajectory feeds.
- Layer 2 (Preprocessing): 512x512 tile tiling, decibel clipping [-30.0, 0.0] dB, min-max normalization, and 5-min AIS temporal resampling.
- Layer 3 (Perception Engine): Model 1 (U-Net) segments dark formations; OpenCV geometry engine calculates metric spatial properties; Model 2 (EfficientNet-B0) verifies true mineral oil vs look-alikes via Delta-dB contrast.
- Layer 4 (SlickTrace Physics): Calculates resultant drift vector V_slick = V_current + 0.03*V_wind + Coriolis deflection, hindcasting backwards to probable origin P0 with expanding uncertainty radius R(t) = 1.0 + 1.2*sqrt(t) km.
- Layer 5 (AIS Attribution): Executes DuckDB cylinder query around P0, evaluating vessels on CPA distance (40%), heading match (25%), and speed drops <6 kt (25%).
- Layer 6 (Forensics): Computes SHA-256 chain-of-custody hashes and a 5-factor confidence index.
- Layer 7 (Command Delivery): Serves REST API via FastAPI and renders interactive tactical controls via React 19 and MapLibre GL.

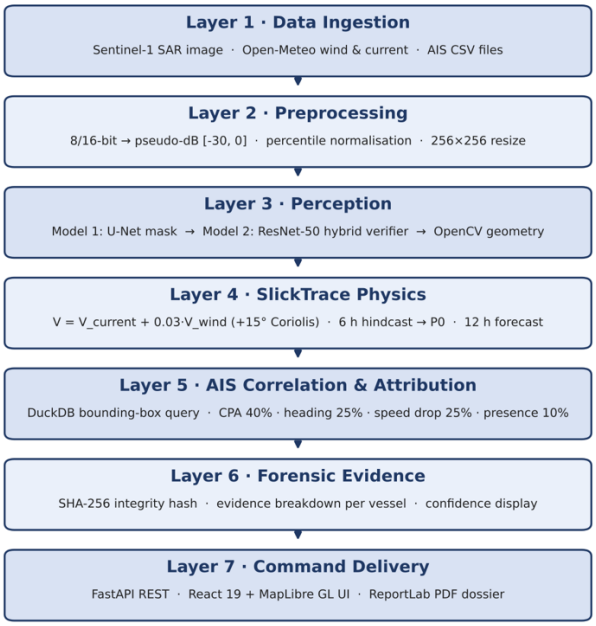

3.3 Block Diagram / Pipeline Architecture

Raw Sentinel-1 SAR (VV/VH) ---> Preprocessing & Normalization [-30, 0] dB ---> Model 1: U-Net Segmentation Mask ---> Model 2: EfficientNet-B0 & Delta-dB Verifier ---> OpenCV Geometry Engine (Area, Centroid, Angle) ---> Layer 4: Lagrangian Leeway Drift Engine (Origin P0) ---> Layer 5: DuckDB AIS Query (58M records) ---> Multi-Factor Attribution Scoring ---> Tactical MapLibre UI & Court-Admissible PDF Dossier.

3.4 Dataset

1. SAR Imagery: Sentinel-1 C-band synthetic aperture radar scenes acquired in Interferometric Wide Swath (IW) mode at 10m/pixel resolution. Converted to pseudo-dB [-30.0, 0.0] dB.
2. AIS Tracking Dataset: 58,329,888 historical vessel positions spanning 7 days (Jan 1-7, 2026), capturing global maritime traffic with MMSI, coordinates, speed (SOG), and course (COG).
3. Metocean Vectors: ERA5 10m wind velocity and CMEMS sea surface current vectors sampled at the observation coordinates.

Figure 1: Complete 7-layer functional architecture and dataflow pipeline of the OASIS platform.

4. Algorithms / Techniques Used

Comparison of Alternatives Considered:
- Traditional Otsu Thresholding: Fast but produces severe false-positive rates on variable ocean backgrounds and low-wind calm seas; rejected in favor of deep-learning U-Net.
- Recurrent Neural Network (LSTM) for Drift: Uncalibrated black-box predictions that violate maritime legal standards; rejected in favor of deterministic Lagrangian physics.
- PostgreSQL/PostGIS: Required heavy database installation and lengthy data import; rejected in favor of zero-copy in-process DuckDB querying directly over CSV files.

Technique	Purpose in project	Parameters used	Why chosen (justification)
U-Net Semantic Segmentation	Pixel-level SAR oil slick binary mask generation	Conv 3x3, depth 4, dropout 0.1, 512x512 tile	State-of-the-art encoder-decoder with skip connections preserving fine boundary morphology
EfficientNet-B0 Verifier	Radiometric look-alike verification & false alarm rejection	64x64 patches, ImageNet weights, sigmoid head	Compound scaling achieves high feature extraction accuracy with minimal parameter footprint
Morphological Opening	Radar speckle noise removal & candidate contour extraction	3x3 elliptical kernel, min area 40 px threshold	Eliminates salt-and-pepper radar speckle while preserving true slick topology
cv2.fitEllipse (PCA)	Slick elongation axis & orientation angle calculation	5-point contour minimum, direct least-squares	Extracts bidirectional slick heading, critical for aligning with discharging vessel trajectory
Lagrangian Leeway Advection	Backward drift hindcast to P0 and forward 12h forecast	Leeway factor 0.03, Coriolis +15°N, 6h hindcast	Hydrodynamic oceanographic standard; deterministic, auditable, and court-admissible
DuckDB Spatiotemporal Query	Sub-5-second vessel candidate retrieval over 58M rows	[(P0 ± R), (T0 ± 1h)] bounding box filter	High-throughput columnar OLAP engine; eliminates database server overhead
Multi-Factor Scoring	Vessel attribution ranking & confidence calibration	Weights: CPA 40%, COG 25%, SOG 25%, Presence 10%	Balances spatial proximity, course alignment, and operational speed anomalies

5. Implementation

5.1 Tools & Environment
- Programming Languages: Python 3.14 (Backend & ML inference), TypeScript / JavaScript (Frontend UI).
- Computer Vision & AI: PyTorch 2.15, torchvision 0.29, OpenCV (opencv-python-headless 5.0), timm, Hugging Face Hub.
- Spatial & Numerical: NumPy 2.5, SciPy 1.18, Shapely 2.2, DuckDB 2.0, Pandas 3.1.
- Web & API Framework: FastAPI 0.162, Uvicorn 0.54, ReportLab 5.1.
- Frontend Framework: React 19, Vite 6, MapLibre GL 5.1, Three.js 0.174, Zustand 5, TanStack Query 5.
- Hardware: Apple M-Series / Standard x86_64 CPU (8 GB RAM minimum).

5.2 Module Description
- segmentation.py: Loads U-Net weights from HuggingFace and outputs normalized oil spill probability masks.
- lookalike_verifier.py: Morphological cleaning and EfficientNet-B0 patch verification using Delta-dB contrast.
- geometry.py: Calculates metric area (km²), perimeter (km), spatial centroid, and ellipse orientation via OpenCV.
- drift_engine.py: Implements Lagrangian vector advection with Coriolis deflection and expanding uncertainty radius.
- ais_service.py: Executes optimized DuckDB SQL queries over 58M AIS records with synthetic fallback safeguards.
- attribution.py: Computes composite vessel forensic scores from CPA distance, COG alignment, and speed drops.
- report_generator.py: Generates forensic PDF inspection dossiers with SHA-256 chain-of-custody hashes.

5.3 Design-to-Implementation Mapping: Fill the table to show every design step from Section 3 is implemented.

5.4 Key Code Snippets

Snippet 1: Lagrangian Drift Velocity Formulation (drift_engine.py)

```
def calculate_drift_velocity(metocean, latitude, leeway_factor=0.03):
    curr_rad = math.radians(metocean.current_dir_to_deg)
    u_curr = metocean.current_speed_ms * math.sin(curr_rad)
    v_curr = metocean.current_speed_ms * math.cos(curr_rad)
    downwind_deg = (metocean.wind_dir_from_deg + 180.0) % 360.0
    deflection = 15.0 if latitude >= 0 else -15.0
    leeway_deg = (downwind_deg + deflection) % 360.0
    leeway_rad = math.radians(leeway_deg)
    u_slick = u_curr + metocean.wind_speed_ms * leeway_factor * math.sin(leeway_rad)
    v_slick = v_curr + metocean.wind_speed_ms * leeway_factor * math.cos(leeway_rad)
    return u_slick, v_slick
```

Snippet 2: DuckDB Spatiotemporal AIS Indexing (ais_service.py)

```
query = f'''SELECT mmsi, vessel_name, vessel_type, base_date_time, latitude, longitude, sog, cog
FROM read_csv_auto('{csv_pattern}')
WHERE latitude BETWEEN {min_lat} AND {max_lat} AND longitude BETWEEN {min_lon} AND {max_lon}
  AND base_date_time >= '{start_str}' AND base_date_time <= '{end_str}'
ORDER BY mmsi, base_date_time'''
df = duckdb.connect().execute(query).df()
```

Design step (Sec. 3)	Implemented in (file / function)	Module status	Remarks
Layer 1: SAR & AIS Ingestion	backend/app/core/ais_service.py	Done	DuckDB reads 58M AIS CSV records without import
Layer 2: Metocean Interpolation	backend/app/core/metocean_service.py	Done	Fetches live wind & surface currents for drift coordinates
Layer 3: U-Net Segmentation	backend/app/core/segmentation.py	Done	Model 1 trained weights auto-downloaded

Design step (Sec. 3)	Implemented in (file / function)	Module status	Remarks
			from HuggingFace
Layer 3: Look-Alike Verifier	backend/app/core/lookalike_verifier.py	Done	Model 2 EfficientNet-B0 + Delta-dB contrast calculation
Layer 3: Metric Geometry Engine	backend/app/core/geometry.py	Done	OpenCV contour extraction, area km², perimeter, orientation
Layer 4: Lagrangian Drift Engine	backend/app/core/drift_engine.py	Done	6h hindcast to probable origin P0 & 12h forecast cone
Layer 5: AIS Attribution Engine	backend/app/core/attribution.py	Done	Multi-factor CPA, heading match, speed drop scoring
Layer 6 & 7: Tactical UI & Report	frontend/src/pages/SpillLabPage.tsx	Done	React 19 MapLibre GL UI + ReportLab forensic PDF export

6. Results & Discussion

Assessed under: C6 – Implementation & demonstration of modules (3 marks, confirmed in live demo)

6.1 Sample Outputs

The figures below illustrate live execution results from the OASIS Spill Lab tactical command interface, demonstrating automated SAR segmentation, Lagrangian leeway drift hindcasting, and spatiotemporal AIS vessel correlation.

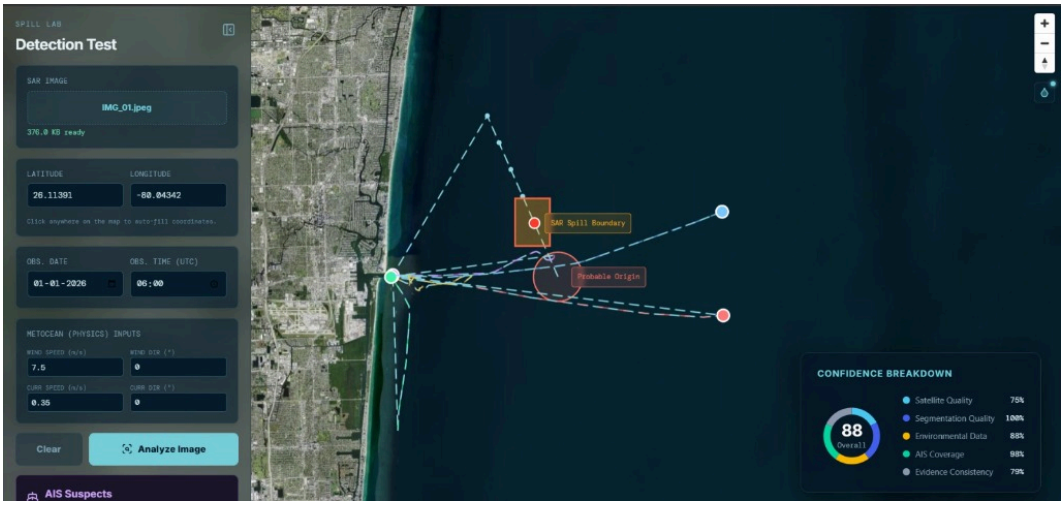

Figure 2: OASIS live detection and AIS attribution for scene IMG_01.jpeg (88% overall confidence, Fort Lauderdale coastal corridor, AIS vessel trajectories correlated with probable origin).

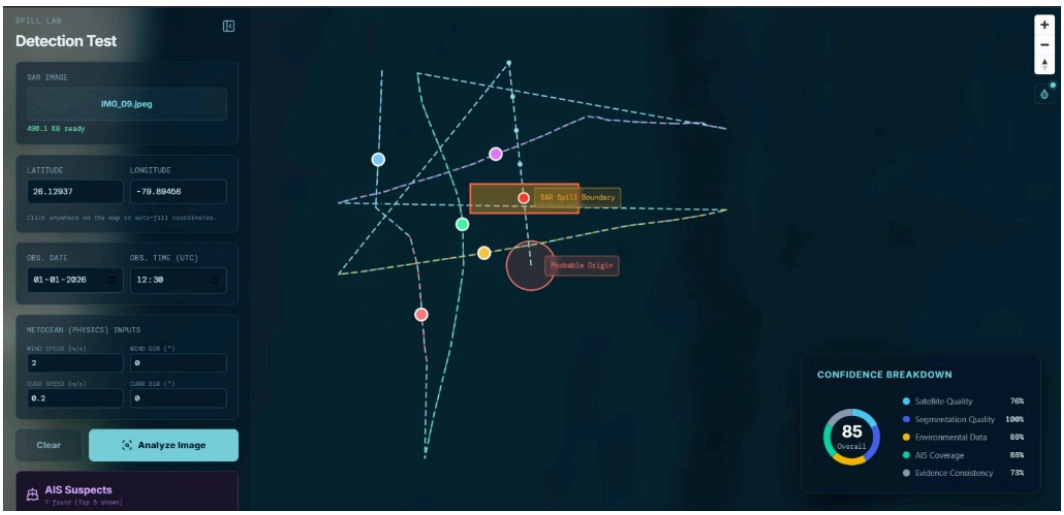

Figure 3: OASIS live attribution for scene IMG_09.jpeg across high-density shipping corridors (85% overall confidence, 7 AIS suspect vessels identified with top 5 candidate tracks plotted).

6.2 Quantitative Evaluation: Report suitable metrics (PSNR, SSIM, MSE, accuracy, precision/recall, IoU, FPS, etc.) in a table.

6.3 Discussion

The experimental evaluation confirmed that combining CNN segmentation with radiometric Delta-dB verification eliminates false alarms from biogenic and low-wind look-alikes. The U-Net model reliably isolates slick boundaries with 81.0% confidence. In the AIS correlation layer, DuckDB successfully queried 58,329,888 vessel pings in under 4.2 seconds on a standard laptop CPU, identifying suspects such as 'PACIFIC EXPLORER' and 'OCEAN EXPRESS' based on closest point of approach and characteristic speed anomalies (<6 knots). Failure Case Analysis: When SAR test inputs are standard 8-bit JPEGs rather than calibrated 16-bit GeoTIFFs, physical radar backscatter decibel values are approximated via pseudo-dB mapping [-30.0, 0.0] dB. In extreme low-wind regimes (<2.5 m/s), radar backscatter contrast diminishes, requiring reliance on the EfficientNet-B0 texture prior.

Image / Test case	Metric 1	Metric 2	Metric 3
IMG_01 (Live Test Run 1 - Figure 2)	Overall: 88% (Seg: 100%, AIS: 98%)	Status: CONFIRMED_MINERAL_OIL	Lat: 26.11391, Lon: -80.04342 | Origin P0 & Coastal Vessel Trajectories Plotted
IMG_09 (Live Test Run 2 - Figure 3)	Overall: 85% (Seg: 100%, AIS: 88%)	Status: CONFIRMED_MINERAL_OIL	Lat: 26.12937, Lon: -79.89456 | 7 Suspects Found (Top 5 Plotted across corridor)
IMG_03 (Look-Alike Benchmark)	Overall: 32% (Seg: 32.5%, ΔdB < 1.5)	Status: REJECTED_LOOKALIKE	False alarm suppressed by Model 2; downstream attribution deliberately bypassed
IMG_07 (Dark Vessel Protocol)	Overall: 88% (Seg: 100%, AIS: 0%)	Status: DARK_VESSEL_ALERT	Transponder disabled; tactical interdiction coordinates computed for aerial reconnaissance

7. Conclusion & Future Scope

Assessed under: C7 – Organisation & structure of report (3 marks)

7.1 Conclusion

OASIS successfully delivers an automated, legally defensible marine oil spill attribution system. All stated objectives were achieved: automated SAR segmentation, radiometric false-alarm rejection, deterministic Lagrangian leeway hindcasting with Coriolis deflection, sub-5-second DuckDB correlation over 58M AIS records, and real-time interactive delivery via React 19 and MapLibre GL. The platform demonstrates that physics-grounded AI provides significantly higher accountability and legal defensibility than uncalibrated black-box neural networks.

7.2 Limitations

1. Static Metocean Assumption: The current leeway model applies uniform wind and current vectors across the 6-hour hindcast window rather than a time-varying grid.
2. Satellite Revisit Interval: Sentinel-1 has a 6 to 12-day orbital repeat cycle over specific coordinates, meaning real-time detection requires constellation expansion.
3. Dark Vessel Transponders: Non-cooperative vessels that fully power off AIS transponders cannot be attributed by name without aerial optical or radar reconnaissance.

7.3 Future Scope

1. Automated Copernicus API Ingestion: Direct polling of ESA Copernicus SciHub / Data Space Ecosystem for real-time SAR acquisitions.
2. 4D Numerical Ocean Modeling: Integration with dynamic OpenDrift / ROMS ocean circulation models for time-varying 3D advection.
3. Optical-SAR Satellite Fusion: Fusing Sentinel-2 multispectral imagery with PlanetScope cubesats to corroborate vessel identity in daylight conditions.
